ResilienceGuard

Business Case / Illustrative only

Commercial opportunity, buyer hypotheses and first-year revenue scenarios. Assumptions are not market-verified prices.

How to read the numbers: revenue is money received; direct costs are the delivery costs tied to customers; gross profit is revenue minus those direct costs; net result also subtracts the assumed fixed business overhead. Figures are before tax.

01 / Opportunity and buyer

Critical operators buy backup products, infrastructure and incident response but still need a cross-system view of whether recovery can succeed. ResilienceGuard would sit above those tools as an assurance layer: inventory, dependency context, scenario assessment and evidence-backed exercises. It is intended to complement a current protection stack.

A likely buyer is a leader responsible for technology (CIO), information security (CISO), operations (COO), risk or continuity. Day-to-day users may work in disaster recovery, backup, security, applications or infrastructure. An initial customer could be a regional hospital group, municipal utility, public service or critical supplier with scattered recovery records and an upcoming exercise.

Deployment choices: customer-hosted on-premises/private cloud for sensitive environments; isolated managed service where data policy allows; or partner-delivered readiness assessment and exercise. Implementation work may cover service catalog mapping, recovery objective normalization, dependency workshops, adapter configuration and a supervised restore rehearsal. Ongoing revenue could include annual licensing, support, reporting and recurring exercises.

- Customer value is measured from the customer's own data: stale/missing recovery points, blocked dependencies, observed restore duration, repeat exercise coverage and evidence preparation time.
- ROI equation: avoided outage hours × customer-validated loss/hour + validated recovery/audit labor saved – license – implementation. Do not substitute generic market averages for customer values.
- Differentiation is a hypothesis: vendor-independent scenario readiness across existing products, including simultaneous cyber and physical disruption. Vendors already sell overlapping capabilities.

02 / Illustrative first-year unit economics

The following are planning assumptions for discussion, not researched market prices, vendor quotes, customer commitments or a forecast. Each first-year customer pays an assumed $18,000 implementation fee, $48,000 annual license and $12,000 annual support: $78,000 first-year revenue. Direct implementation/delivery is assumed at $7,200 and recurring support/hosting at $10,800, or $18,000 total direct cost; resulting gross profit is $60,000 per customer.

Overall net profitability subtracts fixed operating overhead for product engineering, sales, administration, security and legal. The illustrative overhead grows by scale in the table below. Taxes, financing, working capital, churn, customer acquisition cost and renewal rates are excluded; therefore this is a sensitivity sketch, not a company valuation or operating plan.

- Recurring revenue mix per customer: $48,000 license + $12,000 support each year, subject to renewal.
- Implementation is one-time and should be scoped by integration count and exercise complexity.
- Direct costs rise with vendor adapters, data residency, customer-specific security controls and managed service commitments.

Customers	Revenue	Direct costs	Gross profit	Fixed overhead	Net result
1	$78,000	$18,000	$60,000	$260,000	-$200,000
5	$390,000	$90,000	$300,000	$360,000	-$60,000
10	$780,000	$180,000	$600,000	$520,000	$80,000
25	$1,950,000	$450,000	$1,500,000	$750,000	$750,000

Net result = gross profit – fixed overhead. Year-one figures include the assumed implementation fee and one annual license/support contract. All figures are illustrative USD.

03 / Revenue scenarios and validation

The customer counts are annual first-year cohort scenarios. Revenue is cohort count multiplied by $78,000. Direct cost is cohort count multiplied by $18,000. Gross profit is revenue less direct cost. Net profitability is gross profit less assumed overhead. Numbers are USD and rounded to whole dollars.

At small scale this model is loss-making because a product/security team is a fixed cost. At ten customers it reaches a small positive illustrative result; at twenty-five it assumes delivery can scale without proportional fixed cost expansion. In practice, sales cycles, procurement, assurance obligations, integration effort, support load and deployment requirements could materially change every input.

Before investment or price commitments, validate buyer/problem interviews, pilot conversion, time-to-integrate, delivery hours, support effort, legal/security review requirements, renewal willingness and customer-specific outage/labor baselines. A paid pilot can be priced as a scoped implementation with an agreed evidence outcome rather than sold as guaranteed risk reduction.

- Revenue includes implementation and annual license/support in year one; it is not ARR.
- Gross margin shown excludes fixed product, sales, compliance and corporate overhead.
- Net result is pre-tax and excludes financing, depreciation and CAC amortization.
